- 1. Assume $x, y, w, z \in \mathbb{R}^n$ and $A \in \mathbb{R}^{n \times n}$. Denote $\langle A, B \rangle = \sum_{i=1}^n \sum_{j=1}^n A(i,j)B(i,j)$ as the inner product in the Euclidean space.
 - (a) Prove $x^T A y = \operatorname{tr}(A y x^T)$. **Answer**: We have $\operatorname{tr}(A y x^T) = \operatorname{tr}(x^T A y)$, but $x^T A y$ is a scalar so $\operatorname{tr}(x^T A y) = x^T A y$. Therefore $x^T A y = \operatorname{tr}(A y x^T)$.
 - (b) Prove $\langle xy^T, wz^T \rangle = (x^T w)(y^T z)$.

Answer: We can expand the left hand side as follows:

$$\langle xy^{T}, wz^{T} \rangle = \langle \begin{pmatrix} x_{1}y_{1} & \cdots & x_{1}y_{n} \\ \vdots & \ddots & \vdots \\ x_{n}y_{1} & \cdots & x_{n}y_{n} \end{pmatrix}, \begin{pmatrix} w_{1}z_{1} & \cdots & w_{1}z_{n} \\ \vdots & \ddots & \vdots \\ w_{n}z_{1} & \cdots & w_{n}z_{n} \end{pmatrix} \rangle$$

$$= x_{1}y_{1}w_{1}z_{1} + x_{1}y_{2}w_{1}y_{2} + \cdots + x_{1}y_{n}w_{1}z_{n}$$

$$+ x_{2}y_{1}w_{2}z_{1} + x_{2}y_{2}w_{2}z_{2} + \cdots + x_{2}y_{n}w_{2}z_{n}$$

$$\vdots$$

$$+ x_{n}y_{1}w_{n}z_{1} + x_{n}y_{2}w_{n}z_{2} + \cdots + x_{n}y_{n}w_{n}z_{n}$$

$$= x_{1}w_{1}(y_{1}z_{1} + y_{2}z_{2} + \cdots + y_{n}z_{n})$$

$$+ x_{2}w_{2}(y_{1}z_{1} + y_{2}z_{2} + \cdots + y_{n}z_{n})$$

$$\vdots$$

$$+ x_{n}w_{n}(y_{1}z_{1} + y_{2}z_{2} + \cdots + y_{n}z_{n})$$

$$= (x_{1}w_{1} + x_{2}w_{2} + \cdots + x_{n}w_{n})(y_{1}z_{1} + y_{2}z_{2} + \cdots + y_{n}z_{n})$$

$$= (x^{T}w)(y^{T}z)$$

Therefore the two sides are equal, so $\langle xy^T, wz^T \rangle = (x^Tw)(y^Tz)$.

- 2. Let $A \in \mathbb{R}^{n \times n}$ be a symmetric matrix and I_n be an identity matrix in $\mathbb{R}^{n \times n}$. Let $\lambda_1, \ldots, \lambda_n$ be n eigenvalues of A with corresponding eigenvectors u_1, u_2, \ldots, u_n .
 - (a) Prove u_i is an eigenvector of $A 3I_n$ for i = 1, ..., n.

Answer: By definition of eigenvalue, we have $Au_i = \lambda_i u_i$; we can subtract $3u_i$ from both sides:

$$Au_i - 3u_i = \lambda_i u_i - 3u_i \implies (A - 3I_n)u_i = (\lambda_i - 3)u_i.$$

Therefore by definition u_i is an eigenvector of $(A-3I_n)$ with corresponding eigenvalue λ_i-3 .

(b) Prove u_i is an eigenvector of $(A - I_n)(A - 3I_n)$ for i = 1, ..., n.

Answer: From part (a) we have $(A - 3I_n)u_i = (\lambda_i - 3)u_i$, following the same procedure we also have $(A - I_n)u_i = (\lambda_i - 1)u_i$. Then

$$(A - I_n)(A - 3I_n)u_i = (A - I_n)[(A - 3I_n)u_i]$$

$$= (A - I_n)(\lambda_i - 3)u_i$$

$$= (\lambda_i - 3)[(A - I_n)u_i]$$

$$= (\lambda_i - 3)(\lambda_i - 1)u_i.$$

Therefore by definition u_i is an eigenvector of $(A - I_n)(A - 3I_n)$ with corresponding eigenvalue $(\lambda_i - 3)(\lambda_i - 1)$.

(c) Compute $tr((A - I_n)(A - 3I_n))$.

Answer: By part (b) the eigenvalues of $(A - I_n)(A - 3I_n)$ are $(\lambda_i - 3)(\lambda_i - 1)$ for i = 1, ..., n. Then since the trace of a square matrix is the sum of its eigenvalues, we have

$$tr((A - I_n)(A - 3I_n)) = \sum_{i=1}^{n} (\lambda_i - 3)(\lambda_i - 1).$$

(d) Compute $\det((A + I_n)(A - 3I_n))$.

Answer: Following the same procedure as part (b) we know that the eigenvalues of $(A + I_n)(A - 3I_n)$ are $(\lambda_i - 3)(\lambda_i + 1)$ for i = 1, ..., n. Then since the determinant of a square matrix is the product of its eigenvalues, we have

$$\det((A + I_n)(A - 3I_n)) = \prod_{i=1}^{n} (\lambda_i - 3)(\lambda_i + 1).$$

- 3. Denote e_i as the *i*th column of the identity matrix $I_n \in \mathbb{R}^{n \times n}$ for i = 1, ..., n. Let $f(x) = \sum_{i=1}^{10} \|x e_i\|_2^2$ where $x \in \mathbb{R}^n$.
 - (a) Compute $\nabla f(x)$.

Answer:

$$Df(x) = 2\sum_{i=1}^{10} (x - e_i) \implies \nabla f(x) = 2\sum_{i=1}^{10} (x - e_i)^T$$

(b) Compute $\nabla^2 f(x)$.

Answer:

$$\nabla^2 f(x) = D(\nabla f(x)) = 2\sum_{i=1}^{10} 1 = 20$$

(c) Show f(x) is a convex function.

Answer: By part (b), the Hessian is positive semidefinite. Therefore f(x) is convex.

(d) Find the global optimal solution of $\min_x f(x)$.

Answer: Solving $\nabla f(x) = 0$ gives us

$$2\sum_{i=1}^{10} (x - e_i)^T = 0 \implies \sum_{i=1}^{10} x = \sum_{i=1}^{10} e_i \implies x = \frac{1}{10}\sum_{i=1}^{10} e_i.$$

- 4. Let $f(x) = \frac{1}{2} ||Ax b||_2^2 + \frac{1}{2} ||x||_2^2$ where $A \in \mathbb{R}^{10 \times 5}$, $x \in \mathbb{R}^5$ and $b \in \mathbb{R}^{10}$.
 - (a) Prove $\nabla f(x)$ is Lipschitz continuous with Lipschitz constant $L = \|A^T A\| + 1$. Answer: We have

$$Df(x) = (Ax - b)A + x = A^{2}x - Ab + x \implies \nabla f(x) = (A^{2}x - Ab + x)^{T}$$

and

$$\nabla^2 f(x) = D^2 f(x) = A^2 + 1 = ||A^T A|| + 1.$$

Therefore $\nabla f(x)$ is Lipschitz continuous with Lipschitz constant $L = ||A^T A|| + 1$.

(b) Write down the kth iteration of the gradient descent method.

Answer: We have

$$x_k = x_{k-1} - \frac{1}{L} \nabla f(x_{k-1})$$

= $x_{k-1} - \frac{(A^2 x_{k-1} - Ab + x_{k-1})^T}{\|A^T A\| + 1}$.

(c) Write down the kth iteration of Newton's method.

Answer: Our search direction is

$$d_{k-1}^{N} = -\nabla^{2} f(x_{k-1})^{-1} \nabla f(x_{k-1})$$
$$= -(A^{2} + 1)^{-1} (A^{2} x_{k-1} - Ab + x_{k-1})^{T}$$

So

$$x_k = x_{k-1} + d_{k-1}^N$$

= $x_{k-1} - (A^2 + 1)^{-1} (A^2 x_{k-1} - Ab + x_{k-1})^T$.

5. Judge the following sets are whether convex or not.

(a)
$$\Omega = \{(x_1, x_2) : |x_1| + |x_2| \le 1\}$$

Answer: Take $(x_1, x_2), (y_1, y_2) \in \Omega$ and $\alpha \in [0, 1]$, we have

$$|x_1| + |x_2| \le 1 \implies \alpha(|x_1| + |x_2|) \le \alpha$$

and

$$|y_1| + |y_2| \le 1 \implies (1 - \alpha)(|y_1| + |y_2|) \le 1 - \alpha.$$

Adding the two gives us

$$\alpha(|x_1| + |x_2|) + (1 - \alpha)(|y_1| + |y_2|) \le \alpha + (1 - \alpha)$$

$$\implies \alpha(|x_1| + |x_2|) + (1 - \alpha)(|y_1| + |y_2|) \le 1.$$

So $\alpha(x_1, x_2) + (1 - \alpha)(y_1, y_2) \in \Omega$ and therefore Ω is a convex set.

(b)
$$\Omega = \{(x_1, x_2) : x_1^2 + x_2^2 \ge 1\}$$

Answer: Take $(x_1, x_2), (y_1, y_2) \in \Omega$ and $\alpha \in [0, 1]$, we have

$$x_1^2 + x_2^2 \ge 1 \implies \alpha(x_1^2 + x_2^2) \ge \alpha$$

and

$$y_1^2 + y_2^2 \ge 1 \implies (1 - \alpha)(y_1^2 + y_2^2) \ge 1 - \alpha.$$

Adding the two gives us

$$\alpha(x_1^2 + x_2^2) + (1 - \alpha)(y_1^2 + y_2^2) \ge \alpha + (1 - \alpha)$$

$$\implies \alpha(x_1^2 + x_2^2) + (1 - \alpha)(y_1^2 + y_2^2) \ge 1.$$

So $\alpha(x_1, x_2) + (1 - \alpha)(y_1, y_2) \in \Omega$ and therefore Ω is a convex set.

(c)
$$\Omega = \{(x_1, x_2) : x_1^2 + x_2^2 \le 1, x_1 + x_2 \ge 0\}$$

Answer: Take $(x_1, x_2), (y_1, y_2) \in \Omega$ and $\alpha \in [0, 1]$, we have

$$x_1^2 + x_2^2 \le 1 \implies \alpha(x_1^2 + x_2^2) \le \alpha,$$

$$x_1 + x_2 \ge 0 \implies \alpha(x_1 + x_2) \ge 0$$

and

$$y_1^2 + y_2^2 \le 1 \implies (1 - \alpha)(y_1^2 + y_2^2) \le 1 - \alpha,$$

$$y_1 + y_2 \ge 0 \implies (1 - \alpha)(y_1 + y_2) \ge 0.$$

Adding the two gives us

$$\alpha(x_1^2 + x_2^2) + (1 - \alpha)(y_1^2 + y_2^2) \ge \alpha + (1 - \alpha) \implies \alpha(x_1^2 + x_2^2) + (1 - \alpha)(y_1^2 + y_2^2) \ge 1,$$
$$\alpha(x_1 + x_2) + (1 - \alpha)(y_1 + y_2) \ge 0$$

So $\alpha(x_1,x_2)+(1-\alpha)(y_1,y_2)\in\Omega$ and therefore Ω is a convex set.

6. Consider

$$\min_{x_1, x_2} x_1^2 + 2x_2^2 \text{ s.t. } x_1 + x_2 = 1$$

(a) Write down the KKT conditions.

Answer:

$$L(x,\lambda) = x_1^2 + 2x_2^2 - \lambda(x_1 + x_2 - 1) = 0$$

$$\implies \frac{\delta L}{\delta x_1} = 2x_1 - \lambda, \frac{\delta L}{\delta x_2} = 4x_2 - \lambda$$

Then we have

$$ZG: \nabla L(x^*, \lambda^*) = 0 \implies 2x_1^* - \lambda^* = 0, 4x_2^* - \lambda^* = 0$$

$$PF: c(x^*) = 0 \implies x_1^* + x_2^* - 1 = 0$$

$$DF: \lambda^* \ge 0$$

$$CS: \lambda^* c(x^*) = 0 \implies \lambda(x_1^* + x_2^* - 1) = 0.$$

(b) Find the KKT points.

Answer: From ZG we have

$$2x_1^* - \lambda^* = 0, 4x_2^* - \lambda^* = 0 \implies 2x_1^* = 4x_2^* = \lambda^* \implies x_1^* = 2x_2^*,$$

then we can substitute into PF which gives us

$$x_1^* + x_2^* - 1 = 0 \implies x_1^* = \frac{2}{3}, x_2^* = \frac{1}{3}.$$
